Introduction: Spiders belong to the order Araneae of class Arachnida. They are distinguished from other arachnids by their two distinct body regions, the cephalothorax and abdomen, which are connected by a narrow stalk called pedicel (Coddington & Levi, 1991). They are carnivorous hunters often use their webs to trap the prey (Dippennar-Schoeman, 2002). Spiders are gaining importance as ecological indicators due to their extreme sensitivity to natural conditions and anthropogenic disturbances. However, despite of their fundamental roles in most natural ecosystem, they have largely been ignored in conservational studies (Sebastian & Peter 2009). The present checklist provides an overview on Indian spiders.

Global diversity: Spiders have a world-wide distribution, covering all terrestrial habitats except the polar regions. A total of 51,929 species of spiders in 4376 genera and 135 families have been discovered (World Spider Catalog, 2023). Previous studies suggested that spider diversity is expected to be at least 120,000 species worldwide (Agnarsson *et al.*, 2013; Framenau *et al.*, 2014). It indicates that most of the spider diversity remains unexplored and undocumented.

Diversity in India: Presently 1,971 species of spiders under 500 genera and 61 families have been reported from India, which constitute 3.79% of the world's spider population. The families having the highest number of species in India are Salticidae with 317 species, followed by Araneidae with 197 species and Thomisidae with 183 species.

Endemism: Of the total Indian spiders, 1,347 species are endemic to India, accounting for more than 68% of the total Indian spider population.

Habitat: Known for their immense species diversity, spiders are found almost in all habitats. They are found near water bodies, on the ground, in underground caves and mountains, on forest floors, on trees, barks, dead leaves beneath stones, fallen logs, meadows, and grassy fields. Some spiders reside in and near houses while some others frequent human dwellings and outbuildings (Sebastian & Peter 2009). The only places where there are no spiders are the polar regions and the oceans.

Ecological Significance: Spiders are undoubtedly an essential component of global biodiversity, as they perform several key functions in ecosystems as predators and food sources for other animals (Uniyal, 2004). They are exclusively carnivorous and preliminary attack insects and other arthropods. Therefore, spiders play a vital role in controlling insect populations in most terrestrial ecosystems. They are also an important food source for a variety of birds, lizards, and wasps. Spiders are used as ecological indicators because of their susceptibility to ecosystem disturbance as well as their diversity, abundance, and ease of sampling (Clausen, 1986; Scott *et al.*, 2006). They are also useful in determining the overall species richness and health of terrestrial ecosystems (Norris, 1999). Overall, spiders have a major impact on the dynamics of every terrestrial ecosystem (Hsieh, 2011).

Human Significance: Spiders are beneficial to humans in many ways. They act as important biological control agents in agricultural ecosystems (Nyffeler & Sunderland, 2003). So, they play a prominent role in reducing the usage of pesticides in agriculture by eating harmful insects (Riechert & Lockley, 1984). Spider silks are amongst the very finest structural materials produced by nature (Gosline *et al.*, 1986). Synthesized spider silk has proven to be useful in making medical devices, parachutes, bullet-proof vests, and ropes (Xing *et al.*, 2017). Scientists are currently researching the properties of spider venom, and venom peptides have been proven to be useful in medicine and as bio-pesticides (Saez & Herzig, 2019).

Threatened tarantula species: As per the IUCN Red List of Threatened species, 13 species are in the Threatened categories.

Invasive alien species: None of the species reported from India are treated as invasive alien species.

Gap areas: Spiders exhibit a significant level of abundance and diversity across the Indian subcontinent. However, the current state of research pertaining to this taxonomic group is deemed insufficient. Presently, a total of 1,971 species of spiders have been reported from the Indian region. Unfortunately, this number is relatively small compared to other global regions, as India is known for its diverse ecosystems and unique biodiversity. A large number of spiders were reported from the West Bengal, Kerala, Tamil Nadu, Maharashtra, Madhya Pradesh, Assam states of India. But this group is least studied in Dadra Nagar Haveli, Daman & Diu, Chandigarh, Haryana, Delhi, Ladakh, Indian islands, Jharkhand, and North Eastern States. This reflects the fact that many parts of India remain largely unexplored. Therefore, more work needs to be undertaken to explore the actual diversity and distribution of spiders in India.
