CRUSTACEA: COPEPODA

K. Valarmathi, Karuthapandi M, Jeyasree Tilak and Honey U.K. Pillai

valarkamacro@gmail.com; kpandi83@gmail.com

Introduction : Copepods are small aquatic crustaceans and are one of the most numerous metazoan groups in aquatic communities. They are classified under the Phylum Arthropoda, Subphylum Crustacea, Superclass Multicrustacea and Class Copepoda. The Class Copepoda has 10 orders such as Calanoida, Canuelloida, Cyclopoida, Gelyelloida, Harpacticoida, Misophrioida, Monstrilloida, Mormonilloida, Siphonostomatoida, and Platycopioida. Out of the 10 orders of copepods seven orders are reported from India. The Suborder Poecilostomatoida is presently considered as a group under Cyclopoida but phylogenetically separated from it. Members of the orders Calanoida, Cyclopoida and Harpacticoida are important components in marine as well as free living freshwater plankton. Among the marine, pelagic copepods, calanoids dominate (79.2%) the others. The Indian Ocean has the maximum species composition and the Arctic Ocean has the minimum (Boxshall and Halsey, 2004). The suborder Ergasilida (=Poecilostomatoida) of the order Cyclopoida, the orders Siphonostomatoida and Monstrilloida are mostly parasitic either in their adult or larval stages (Roy, 2019).

Adult copepods typically have a body length of 1-2 mm, but adults of free-living species may be as short as 0.2 mm or as long as 17 mm. In case of parasitic forms on large vertebrate hosts, body lengths may exceed 20 cm. Ecologically the planktonic copepods provide functionally important links in the aquatic food chain feeding on the microscopic algal cells of the phytoplankton and, in turn, being eaten by juvenile fish and other planktivores, including some whales. In fresh water, copepods have the potential to act as a biological control mechanism for malaria by consuming mosquito larvae. However, they also serve as intermediate hosts for many animal parasites and even parasites of humans, including the fish tapeworm and guineaworm.

Copepods are important secondary producers or primary consumers and ultimately contribute significantly to the food chain in large ecosystems. Almost all types of marine organisms, directly or indirectly depend on these small organisms for their food. Copepods form important food for many

marine fishes and invertebrates. Copepods of aquaculture importance mainly belong to the orders Calanoida, Cyclopoida and Harpacticoida. Harpacticoids are more numerous in species and occupy more than 50% of the total species of copepods. Generally, harpacticoids are benthic with a wide variety of food habits from filter feeding to detritus feeding. There are many predatory and parasitic forms also available in this group (Boxshall and Halsey, 2004 and Dussart, and Defaye 2001). Copepods are sometimes used as biodiversity indicators.

The studies on Indian copepods were initiated by Steenstrup and Lütken (1861) with the description of two parasitic copepods. Sewell (1912) has started the inventory of Indian planktonic copepods and made a significant contribution through his series of publications. It is followed by a several renowned researchers (see Roy and Venkataraman, 2018, Roy 2018, 2019).

Global diversity: Globally there are about 13000 nominal species of copepods are known so far, most of them are found in marine environment and nearly about 3000 species inhabit freshwater (Boxshall and Defaye, 2008; Ranga Reddy, 2017). However, still the global diversity is not assessed exactly and there is no comprehensive list of species.

Diversity in India : The catalogues published by Roy and Venkataraman (2018) and Roy (2018,2019) stated the availability of 287 species and subspecies of Calanoids belonging to 82 genera and 25 families; 181 species and subspecies of Cyclopoida under 38 genera and 9 families; 403 species and subspecies of Harpacticoida belonging to 163 genera and 35 families; 535 species of parasitic copepods belonging to the orders Poecilostomatoida, Siphonostomatoida and Monstrilloida. In the present study the already known species were updated and the recently described species were added. In this checklist a total of 1543 species and subspecies of Copepods belonging to 458 genera, 117 families and seven orders were documented from India (Table 1). Of which, the order Calanoida dominates with 495 species belonging to 114 genera and 30 families. The order Canelloida is represented by 18 species belonging to 8 genera and 2 families. The order Cyclopoida has 382 species belonging to 105 genera and 31 families. The Order Harpacticoida is represented by 354 species belonging to 152 genera and 32 families. Siphonostomatoida is represented by 281 species comprising of 73 genera and 20 families. The order Monstrilloida with its single family has 12 species under four genera. Similarly the order Mormonilloida is also represented by a single family with two species and two genera (Table 2). The species diversity is more in marine environment than in freshwater. The state wise species distribution shows that the highest number of copepods were recorded from Andaman and Nicobar (426 species),

Tamil Nadu (366 species), Kerala (284 species), and Andhra Pradesh (260 species). Whereas, there is no exploration and documentation of copepods from certain Northeastern states of India, such as Arunachal Pradesh, Mizoram, Nagaland and some of the Union territory like Chandigarh, Daman & Diu, and Ladakh. The lowest number of only one species reported from the state of Manipur and Sikkim (Table 2).

Table 1. Diversity of Indian Copepods

Sl. No.	Order	Family	Genera	Species

Endemism: More than 30 species of copepods are endemic to India, it includes 13 species of Calanoida and nine species of Cyclopoida and more than 13 species of Harpacticoida in freshwater environment. *Pseudodiaptomus lobipes* is an endemic marine copepod and the endemicty of other species are yet to be assessed. The high diversity endemism around 50% of copepods reported from Indian ocean, which includes marine and backwaters. However, their status is yet to be assessed with systematic exploration and taxonomic investigation.

Habitat: Copepods are a group of small crustaceans found throughout the world's natural and man-made aquatic environments, spanning the entire salinity range from fresh water to hypersaline water, including the most unusual continental habitats. Copepods inhabit almost every aquatic biotope, as well as semiterrestrial habitats such as mosses and humid forest soils. Some species are planktonic (inhabiting sea waters), some are benthic (living on the ocean floor), a number of species have parasitic phases, and some continental species may live in limnoterrestrial habitats and other wet terrestrial places, such as swamps, under leaf fall in wet forests, bogs, springs, ephemeral ponds, puddles, damp moss, or water-filled recesses of plants (phytotelmata) such as bromeliads and pitcher plants. Many live undergrounds in marine and freshwater caves, sinkholes, or stream beds.

Gap areas : Among the phylum Arthropoda, most of the taxonomic studies focuses on class Insecta with various expertise on each order. After the class Insecta, crustacean copepods are the more diverse group with a greater number of species among the faunal diversity. Documentation of freshwater

copepods are very limited and scattered. There is no exploration and documentation of copepods from Northeastern States like Arunachal Pradesh, Mizoram, Nagaland and some of the Union territory like Chandigarh, Daman & Diu, Ladakh. There is only one species reported from the state of Sikkim. However, Indian copepods are very much neglected taxonomic group when compared to other faunal studies in India. It might be due to their smaller size, scattered literatures, lack of sophisticated microscope facilities and qualified researchers to train the youngsters. It is emphasized that Indian copepods need adequate attention among the taxonomist, serious revision and exploration to bringout the actual diversity of species.

Systematic list of Indian Copepods

	Phylum : ARTHROPODA Gravenhorst, 1843 Subphylum : CRUSTACEA Brünnich, 1772 Class : COPEPODA Milne Edwards, 1840 Infraclass : NEOCOPEPODA Huys & Boxshall, 1991 Superorder : GYMNOPLEA Giesbrecht, 1882 Order : CALANOIDA Sars G.O., 1903 Family Acartiidae Sars G.O. 1903
