Introduction: The order Siphonaptera, popularly known as “fleas” are wingless ectoparasites of birds and mammals. They are laterally flattened and hind legs are evolved for jumping. They are highly host specific. The mouth parts are adapted for piercing and sucking the blood of the host. Unlike other insects, they lack compound eyes and instead have eye spots. They are holometabolous insects. Mated female lays eggs on the substrate of host's nest or burrow. The larvae feed on organic matter and pupate. The pupae can remain dormant for a long time till a suitable environmental condition arise.

Global diversity: Globally 2229 species under 259 genera and 8 families are known.

Diversity in India: In India 68 species under 35 genera and 2 families are known.

Endemism: Nine species are reported to be endemic to India.

Habitat: Adults are ectoparasites of birds and mammals. Larvae are found in the nest and burrows of the host.

Ecological Significance: Fleas are ectoparasites of vertebrates and transmit many diseases.

Human Significance: Fleas are vectors of many bacterial, rickettsial, protozoal and helminthic and viral diseases in humans and animals including bubonic plague.

Threatened species: No species are reported as threatened in India.

Protected Species as per WPA (2022): Species reported from India are not listed under any Schedules of the Wildlife Protection Act.

Species under CITES: Species reported from India are not listed under CITES.

Invasive alien species: No invasive alien species are reported from this order.

Gap areas: Extensive surveys are required to understand the distribution of fleas among different vertebrate hosts.
