## **Introduction**

Diapriids (Diapriidae: Hymenoptera) and proctotrupids (Proctotrupidae: Hymenoptera) are diverse groups of parasitic wasps having a wide distribution globally. They are primarily solitary or gregarious endoparasitoids of dipteran larvae and pupae, though a few are also known to attack ants and staphylinid beetles (Yoder, 2004). They are often encountered in varied habitats including meadows, grasslands, cultivated lands and also forested areas (Rajmohana, 2006). They often abound in areas with decaying vegetation and fungi. Due to their small size (an average size of 2-3mm), they often remain unnoticed. Characters like a non-metallic shiny black body, 11 to 15-segmented antennae that emerge atop a protuberance on forehead; two-segmented trochanters and a much reduced wing venation define the group. Over 4000 species of diapriids are estimated to occur in the world, though very few have been described formally (Masner, 1993).

Diapriidae was placed under Superfamily Proctotrupoidea (Masner, 1993) for a long time, until the recent. The extant Hymenoptera was reclassified by Sharky (2007), based on phylogenetic studies. As of now, families Diapriidae, Monomachidae and Maamingidae together constitute superfamily Diaprioidea, where as families Austroniidae, Heloridae, Pelecinidae, Peradeniidae, Proctotrupidae, Proctorenyxidae, Roproniidae and Vanhorniidae remain under superfamily Proctotrupoidea. Only Diapriidae and Proctotrupidae are speciose in India.

The following checklist deals with 104 species of Diapriidae and 4 species of Proctotrupidae known from India.

*Basalys nilgiriensis*  
(Diapriidae)

*Phaenoserphus sureshii*  
(Proctotrupidae)
